BACTERIAL NITROREDUCTASE FOR THE REDUCTION OF CB 1954 AND ANALOGUES
THEREOF TO A CYTOTOXIC FORM

THIS INVENTION relates to the control of neoplastic tissue growth and is particularly concerned with the provision of new anti-tumour agents and with enzymes capable of converting 5 prodrugs into anti-tumour agents.

The alkylating agent 5-(aziridin-1-yl)-2,4-dinitrobenzamide (hereinafter designated CB 1954) has been known, almost for 20 years, as an interesting experimental compound of unique selectivity. Although CB 1954 is structurally quite closely related to numerous other known alkylating agents which have a relatively broad range of activity, CB 1954 exhibits considerable activity against the Walker tumour cells in vivo or in vitro but was thought to be virtually inactive against other tumours.

15 It was recently discovered that the selectivity of CB 1954 arose from the fact that it was not an anti-tumour agent per se but was a prodrug for an anti-tumour agent generated from CB 1954 by a nitroreductase enzyme found in the Walker cell. This nitroreductase from the Walker cell was subsequently shown to 20 be an enzyme known from other sources which was an NAD(P)H dehydrogenase (quinone) classified as EC.1.6.99.2, see Robertson et al, J. Biol. Chem. 261, 15794-15799 (1986).

In the course of the previous investigations with CB 1954, it was found that the Walker cell enzyme EC.1.6.99.2 had the 25 ability to reduce the 4-nitro group of CB 1954 to the corresponding hydroxylamine and that it was the resulting 5-(aziridin-1-yl)-2-nitro-4-hydroxylamino-benzamide that was the active anti-tumour agent.

The use of prodrugs represents a clinically very valuable 30 concept in cancer therapy since, particularly where the prodrug is to be converted to an anti-tumour agent under the influence of an enzyme that is linkable to a monoclonal antibody that will bind to a tumour associated antigen, the combination of such a prodrug with such an enzyme monoclonal/antibody

conjugate represents a very powerful clinical agent.

We have now discovered new nitroreductases, obtainable from bacterial sources, that are of interest in that not only are they capable of converting CB 1954 into an active anti-tumour agent, but also, unlike EC.1.6.99.2, capable of converting CB 1954 analogues which are also prodrugs into active anti-tumour agents.

Description of the Drawings

Figure 1 shows the results of an experiment in which CB 1954 (100 μ M) and reduced cofactor (500 μ M) were incubated with enzyme (2mg/ml) *E. coli* nitroreductase (A) or 25 μ g/ml Walker DT diaphorase (B) in 10mM sodium phosphate buffer (pH7) in air at 37°C. At various times aliquots (10 μ l) were injected onto a Partisil SCX (240 x 4.7mm) HPLC column and eluted isocratically (2ml/min) with 100mM NaH₂PO₄. The eluate was continuously monitored for absorption at 320, 260 and 360 nm and the concentration of CB 1954 calculated by integration of the peak corresponding to this compound on the HPLC trace.

Figure 2 shows the formation of actinomycin D (AMD) during incubation of an AMD prodrug with a nitroreductase of the present invention.

Figure 3 shows the formation of mitomycin C (MC) during incubation of an MC prodrug with a nitroreductase of the present invention.

Figure 4 shows the binding in vitro of an antibody-enzyme conjugate according to the invention to cells.

The present invention provides a nitroreductase, obtainable from a bacterium having the following characteristics as exemplified by examples isolated from *Escherichia coli* B and *Bacillus amyloliquifaciens*:

1. It is a flavoprotein having a molecular weight in the range 20-60 Kilodaltons;
2. It requires either NADH or NAD(P)H or analogues thereof as

a cofactor.

3. It has a K_m for NADH or NAD(P)H in the range 1-100 μ M.

4. It is capable of reducing either or both nitro groups of CB 1954 and analogues thereof to a cytotoxic form e.g. the hydroxylamine.

The nitroreductases of the invention occur naturally within the cells of *E. coli* B, *E. coli* C and other *E. coli* strains e.g. K12 type as well as other gram negative organisms e.g. *Thermus aquaticus*, and gram positive bacteria such as *Bacillus amyloliquifaciens* and *Bacillus caldoteanax*. They can be recovered from such cells by disrupting the cells and subjecting the cell contents to chromatographic separation and isolating the nitroreductase.

15 For example, the nitroreductase of the present invention from *E. coli* B has been purified to homogeneity - see Table 1 and has been subjected to amino acid sequence analysis with the results set out in Table 2. The upper sequence shows the deduced amino acid sequence of the 219-mer nitroreductase
20 obtained from *Salmonella typhimurium* as described by Watanabe *et al*, Nucl. Acids, Res. 18, 1059 (1990). The lower sequence in bold type shows the sequence of the cyanogen bromide fragments of the *E. coli* B nitroreductase as an example of the present invention showing a certain degree of homogeneity but
25 sufficient differences to confirm that it is nitroreductase that is different from that of Watanabe *et al* and the recently described *Enterobacter cloacae* nitroreductases, see Bryant *et al*, J. Biol Chem. 266, 4126 (1991) or the Walker cell nitroreductase and is a previously unreported enzyme.

30 The amino acid sequence of the *E. coli* B nitroreductase of the invention can also be derived from sequencing the nucleotides in the nitroreductase gene and these sequences are set out below in Table 3. The nucleotide sequence of Table 3 has been used to prepare the attached sequence listings.

Using the information in Table 3, a nitroreductase according to the present invention may be prepared by expressing DNA encoding the nitroreductase in a suitable expression vector contained in a host cell, and recovering the nitroreductase.

- 5 The expression vector may be, for example, a bacterial, yeast, insect or mammalian expression vector and the host cell will be selected to be compatible with the vector.

As indicated above, the new enzymes of the present invention are capable of reducing a nitro group in various substrate
10 molecules and we have found that the enzymes are particularly useful in their ability to reduce the nitro group of various p-nitrobenzyloxycarbonyl derivatives of cytotoxic compounds to give "self-immolative" compounds that automatically decompose to release cytotoxic compounds.

- 15 The interest in the present approach resides in the fact that the cytotoxicity of various cytotoxic compounds containing amino or hydroxy substituents, particularly aromatic amino or hydroxy substituents give rise to p-nitrobenzyloxycarbonyl derivatives of the amino or hydroxy group which exhibit
20 considerably less cytotoxicity than the amino or hydroxy parent compound. Thus, it is possible to use the p-nitrobenzyloxycarbonyl derivatives as prodrugs in a system of the type discussed above where the prodrug is converted into an anti-tumour agent under the influence of an enzyme that is
25 linkable to a monoclonal antibody that will bind to the tumour associated antigen.

Accordingly, the present invention provides new compounds of the general formula:

and:

where R^1 and R^2 are groups such that the compound R^1NH_2 and R^2OH are cytotoxic compounds.

It is preferred that compounds R^1NH_2 and R^2OH are aromatic cytotoxic compounds and the compounds R^1NH_2 can be any one of the well known nitrogen mustard compounds, for example based on p-phenylene diamine. Thus, the compound R^1NH_2 can be:

or analogues of this compound with the general structure IV

where R' and R'' are H, F or CH_3 , and particularly where

$\text{R}' = \text{H}$ and $\text{R}'' = \text{CH}_3$;

or $\text{R}' = \text{CH}_3$ and $\text{R}'' = \text{H}$;

or $\text{R}' = \text{H}$ and $\text{R}'' = \text{F}$;

or $\text{R}' = \text{F}$ and $\text{R}'' = \text{H}$.

A further type of amino cytotoxic compound that can be used in accordance with the present invention are compounds such as actinomycin D, doxorubicin, daunomycin and mitomycin C. The structure of the pro-drugs derived from actinomycin D, doxorubicin and mitomycin C are shown below as V, VI and VII respectively.

VII

SUBSTITUTE SHEET

Similar p-nitrobenzyloxy derivatives can be made at the amino substituent of other actinomycins and of the other cytotoxic compounds of the type mentioned above.

In addition to forming p-nitrobenzyloxycarbonyl derivatives at an amino group on a cytotoxic compound, similar derivatives can be made at a hydroxy group, particularly a phenolic hydroxy group of a cytotoxic compound. Here, attention is directed at the phenolic nitrogen mustard compounds, and a specific compound of the invention of this type is of the formula:

In a further aspect of the invention, we have determined that the new enzymes of the present invention are capable not only of reducing at least one of the nitro groups of CB 1954 but also at least one of the nitro groups of certain CB 1954 analogues, e.g. descarboxamido CB1954 (1-aziridin-1-yl-2,4-dinitrobenzamide - known as CB 1837) and N,N-dimethyl CB 1954 [N,N-dimethyl-(5-aziridin-1-yl-2,4-dinitrobenzamide also known as CB 10-107)]. The new enzymes of the present invention are also capable of reducing the nitro groups of other aromatic nitro compounds such as 5-chloro-2,4-dinitrobenzamide, 3,5-dinitrobenzamide, 3-nitrobenzamide, 4-nitrobenzamide and 5-nitro-2-furaldehydesemicarbazone (nitrofurazone).

As indicated above, the nitroreductases of the present invention are capable of converting CB 1954 into 2-hydroxylamino-4-nitro-5-(aziridin-1-yl)benzamide which is an active anti-tumour agent and the present invention extends to such 2-hydroxylamino compounds together with its acylated and etherified derivatives. That is to say, the present invention

provides compounds of the general formula IX:

5

IX

10 wherein R^3 is H, an acyl group or a hydrocarbyl group containing up to 6 carbon atoms. By acyl group, we mean a carboxylic acyl group R^4CO where R^4 is a hydrocarbyl group containing 1 to 6 carbon atoms, e.g. an alkyl, alkenyl or phenyl group. The hydrocarbyl group R^3 can be a C_{1-6} alkyl,
15 alkenyl or phenyl group.

The present invention also provides hydroxylamino derivatives of the general formula X:

20

X

25

wherein X^1 and X^2 , which may be the same or different, are each $NHOR^5$ or NO_2 with the proviso that X^1 and X^2 are not both NO_2 , where R^5 is H or a carboxylic acyl or hydrocarbyl group as defined above in relation to formula IX and Y is H or
30 $CON(CH_3)_2$. In the compounds of formula X containing two hydroxylamino groups, the group R can be the same or different but will normally be the same.

As mentioned above, the new p-nitrophenylbenzyloxy compounds of the invention of formulae I and II are of interest in that they
35 have a reduced cytotoxicity compared to that of the cytotoxic compound R^1NH_2 or R^2OH from which they are derived and they are

capable of acting as a substrate for the nitroreductase of the present invention. While the present invention is not dependent, for its definition, upon the exact mode of action of the nitroreductase on the compound of formula I or II, it is
 5 believed that the nitro group of the p-nitrophenyl-benzyloxy-carbonyl residue is converted to the corresponding amino or hydroxylamino group and that the resulting p-aminobenzyloxy-carbonyl or p-hydroxyl-aminobenzyloxycarbonyl compound automatically degrades under the reaction conditions used for
 10 the enzymatic reduction to release the cytotoxic compound and form p-aminobenzyl alcohol or p-hydroxylaminobenzyl alcohol and carbon dioxide as by products in accordance with the following reaction scheme:

The p-nitrobenzyloxycarbonyl compounds of the invention are conveniently prepared by methods of chemical synthesis known
 25 per se. For example, the amine or hydroxy cytotoxic compounds can be reacted with 4-nitrobenzyl chloroformate under anhydrous conditions in the presence of a hydrogen chloride acceptor, particularly an alkylamine such as triethylamine. This reaction can be carried out in a dry organic solvent such as
 30 chloroform and the resulting compound of the invention of formula I or formula II isolated from the organic solvent by conventional methods such as chromatography.

The new compounds of the present invention IX and X will normally be prepared by subjecting the corresponding dinitro
 35 compound to the action of the new nitroreductase of the present

invention. It is, of course, also possible to produce the new compounds of the present invention IX and X by chemical synthesis, using selective reducing agents followed by conversion of the resulting hydroxylamine to its corresponding ester or ether. The esters and ethers are more conveniently prepared semi-synthetically by carrying out the reduction of the nitro group with the nitroreductase of the present invention to give the corresponding hydroxylamine that is then converted by known chemical methods to the corresponding ester or ether.

One of the most convenient ways of producing the new nitroreductase of the invention is to recover the material from the cell contents of bacteria such as E. coli B. Alternatively, it is possible to clone the gene, isolatable from the bacteria, encoding the desired enzyme and to transfer the cloned gene, in a suitable vector system, into another host cell from which or in which it can be expressed.

In order to bring about the enzymatic reduction of CB 1954 and its analogues with the new enzymes of the present invention, it is necessary to have a cofactor present in the reaction system.

The ability of the enzyme of the present invention to bring about this reduction can be demonstrated experimentally by the use of NADH or NAD(P)H as the cofactor but the use of such cofactors in clinical practice may be problematic in view of the ease with which NAD(P)H particularly is oxidised by other enzymes present in the body and the lack of selectivity of the cofactors between the various mammalian and non-mammalian enzymes. We have now found that the riboside of 1,4-dihydro-nicotinic acid is as least as effective as a cofactor in the nitroreductase reduction of CB 1954 and analogues thereof and moreover, because of its selectivity to the E. coli nitroreductase of the invention, is more suited to clinical use which makes its incorporation in a multi-component system of the type described below particularly valuable.

The riboside of 1,4-dihydro-nicotinic acid which can be used in the present invention as a cofactor is a new compound and forms

part of the present invention. It can be prepared from commercially available nicotinic acid ribotide which is first converted to the corresponding riboside by enzymatic dephosphorylation e.g. using an alkaline phosphatase. The
5 riboside, obtained by such enzymatic dephosphorylation, or by chemical synthesis, using the method described by Jarman, J. Chem. Soc. (c) 918-920 (1969) can then be reduced, e.g. using an alkali metal hydrosulphite, to give 1,4-dihydro-nicotinic acid riboside.

- 10 One of the most important practical applications of the new enzymes of the present invention is that they can be used in association with nitro compounds that are prodrugs for anti-tumour agents and so provide a system of cancer chemotherapy where the extent of exposure of the patient to the cytotoxic
15 agent is limited, so far as possible, to those regions where there is the interaction between the prodrug and the nitroreductase of the invention. Thus, one aspect of the present invention is to provide a method of chemotherapy and a system for chemotherapy involving the conjoint use of the
20 nitroreductase of the present invention in association with a nitro compound which is a prodrug for a cytotoxic compound.

The most or one of the most convenient ways of utilising the system of the present invention is to conjugate the nitroreductase of the present invention to a targeting agent
25 such as a monoclonal antibody that will bind with a tumour-associated antigen.

As used herein, the term "monoclonal antibody" will be understood by those of skill in the art not simply to refer to antibodies produced by traditional hybridoma techniques, but
30 also to cover antibodies and variants thereof produced by recombinant means. These include, for example, humanised antibodies such as those with a constant region from a human antibody grafted onto a non-human antibody variable region (see for example EP-A-O 120 694), chimeric antibodies such as those
35 with non-human complementarity determining regions (CDRs) grafted into a human variable region framework (see for example

EP-A-0 239 400) and single chain antibodies. Fragments of such monoclonal antibodies which retain their target binding activity are also included by the general term "monoclonal antibody". This includes Fab' and F(ab')₂ fragments.

5 The selection of monoclonal antibody will clearly be influenced by the nature of the target tumour but for the purposes of illustrating the present invention, reference may be made to the anti-CEA antibody A₅B₇.

As an alternative to the use of a monoclonal antibody, it is
10 also envisaged that other targeting agents to which the nitroreductase of the present invention is conjugated may be used. For example, it is known that certain soluble macromolecules can be used for passive tumour targeting of certain tumour types. Many solid tumours possess vasculature
15 that is hyperpermeable to macromolecules. Although the reasons for this are not clearly understood, the result is that such tumours can selectively accumulate circulating macromolecules. The enhanced permeability and retention effect (EPR effect) is thought to constitute the mechanism of action of SMANCS
20 (styrene/maleic-anhydride-neocarzinostatin), now in regular clinical use in Japan for the treatment of hepatoma. Another class of conjugates under investigation for anticancer activity is N-(2-hydroxypropyl)methacrylamide copolymer-anthracycline conjugates (L. Seymour, Critical Reviews in Therapeutic Drug
25 Carrier Systems, 9(2) 135-187 (1992)). Thus, conjugates of a polymer, including styrene/maleic-anhydride or N-(2-hydroxypropyl)methacrylamide copolymer, and the nitroreductase of the invention can be used place of conjugates of a monoclonal antibody and enzyme.

30 With this system, it is possible in a course of cancer chemotherapy to administer to the patient requiring the treatment the nitro compound which is the prodrug for the cytotoxic compound and the enzyme/targeting agent conjugate. The prodrug and the conjugate can be administered
35 simultaneously but it is often found preferable, in clinical

- practice, to administer the enzyme/agent conjugate before the prodrug, e.g. up to 72 hours before, in order to give the enzyme/agent conjugate an opportunity to localise in the region of the tumour target. By operating in this way, when the
- 5 prodrug is administered, conversion of the prodrug to the cytotoxic agent tends to be confined to the regions where the enzyme/agent conjugate is localised, i.e. the region of the target tumour and damage to healthy cells caused by the premature release of the cytotoxic agent is minimised.
- 10 The degree of localisation of the enzyme/agent conjugate (in terms of the ratio of localized to freely circulating active conjugate) can be further enhanced using the clearance and/or inactivation systems described in W089/10140. This involves, usually following administration of the conjugate and before
- 15 administration of the prodrug, the administration of a component (a "second component") which is able to bind to the such part of the conjugate so as to inactivate the enzyme and/or accelerate the clearance of the conjugate from the blood. Such a component may include an antibody to the
- 20 nitroreductase of the invention which is capable of inactivating the enzyme.

- The second component may be linked to a macromolecule such as dextran, a liposome, albumin, macroglobulin or a blood group O erythrocyte so that the second component is restrained from
- 25 leaving the vascular compartment. In addition or as an alternative, the second component may include a sufficient number of covalently bound galactose residues, or residues of other sugars such as lactose or mannose, so that it can bind the conjugate in plasma but be removed together with the
- 30 conjugate from plasma by receptors for galactose or other sugars in the liver. The second component should be administered and designed for use such that it will not, to any appreciable extent, enter the extravascular space of the tumour where it could inactivate localised conjugate prior to and
- 35 during administration of the prodrug.

The exact dosage regime will, of course, need to be determined by individual clinicians for individual patients and this, in turn, will be controlled by the exact nature of the prodrug and the cytotoxic agent to be released from the prodrug but some
5 general guidance can be given. Chemotherapy of this type will normally involve parenteral administration of both the prodrug and the enzyme/agent conjugate and administration by the intravenous route is frequently found to be the most practical.

Bearing in mind the manner in which the enzymes of the present
10 invention are to be used, the present invention extends to pharmaceutical compositions comprising the enzyme, preferably conjugated to a targeting agent such as a monoclonal antibody capable of binding to a tumour-associated antigen in association with a pharmaceutically acceptable carrier or
15 diluent, normally one suitable for parenteral administration.

The present invention also extends to pharmaceutical compositions comprising one or more of the p-nitrobenzyloxycarbonyl compounds of the present invention of formula I, formula II, formula V, formula VI or formula VII in
20 association with a pharmaceutically acceptable carrier or diluent, normally one for parenteral administration.

The present invention further extends to pharmaceutical compositions comprising the hydroxylamino anti-tumour agents of the present invention of formula IX or formula X in association
25 with a pharmaceutically acceptable carrier or diluent, normally one for parenteral administration.

The present invention also provides a system for use in the control of neoplasia in a human or animal subject comprising the nitroreductases of the present invention, preferably
30 conjugated with a targeting agent such as monoclonal antibody that will bind to a tumour-associated antigen, in association with at least one of a p-nitrobenzyloxycarbonyl compound of Formula I, II, V, VI or VII which is a prodrug for an anti-tumour agent and preferably a riboside or ribotide of nicotinic
35 acid or nicotinamide to act as a cofactor for the enzyme. The

present invention extends to a method of treating neoplasia in a human or animal host requiring such treatment which comprises administering to the host an effective amount of a p-nitrobenzyloxycarbonyl compound of Formula I, II, V, VI or VII which is a prodrug for an anti-tumour agent and the enzyme of the present invention, preferably conjugated with a targeting agent such as a monoclonal antibody that will bind to a tumour-associated antigen, the enzyme preferably being used in association with an ribotide or riboside of nicotinic acid or nicotinamide as cofactor for the enzyme.

The present invention further provides a system for use in the control of neoplasia in a human or animal subject comprising a nitroreductase of the present invention, preferably conjugated with a targeting agent such as a monoclonal antibody that will bind to a tumour-associated antigen, in association with a nitro compound which is a prodrug for an anti-tumour agents of the formula IX or X and preferably a riboside or ribotide of nicotinic acid or nicotinamide to act as a cofactor for the enzyme. The present invention also provides a method of treating neoplasia in a human or animal host requiring such treatment which comprises administering to the host an effective amount of a nitro compound which is a prodrug for an anti-tumour agents of the formula IX or X and the enzyme of the present invention, preferably conjugated with a targeting agent such as a monoclonal antibody that will bind to a tumour-associated antigen, the enzyme preferably being used in association with an ribotide or riboside of nicotinic acid or nicotinamide as cofactor for the enzyme.

The various systems for use in the treatment of neoplasia described above optionally include the "second component" for accelerated clearance described above. Likewise, the methods of treatment of neoplasia described above optionally include as part of that method the use of the second component, an effective amount of which is administered after administration of the enzyme, in order to increase the ratio of localised to freely circulating enzyme. Reference may be made to WO89/10140 for further particular details of the second component, and

such details can be incorporated for use in the present invention.

The present invention is further illustrated by the following Examples.

EXAMPLE I

Isolation and purification of a nitroreductase enzyme from E. coli B.

200 grams of E. coli B cell paste were resuspended to a total
5 volume of 1 litre of 20mM potassium phosphate buffer, pH 7,
containing 0.3M ammonium sulphate. The cells were broken
ultrasonically using an MSE Soniprep 150 disintegrator (3 x 30
seconds on full power with 60 second intervals to allow heat to
dissipate). To aid clarification of the extract, DNase (23,000
10 Kunitz units/L) and RNase (2,400 Kunitz units/L) were added
prior to centrifugation at 8,000g for 30 minutes to remove cell
debris. The clear yellowish supernatant was passed through a
0.45µm filter prior to chromatography.

The filtered extract was applied to a column
15 (25 x 5 cm) of Phenyl-Sepharose CL-6B (Pharmacia) in 20mM
potassium phosphate buffer, pH 7, containing 0.3M ammonium
sulphate. After washing with 2 column volumes of starting
buffer, the column was eluted with 10mM Tris-HCl buffer, pH
7.6. Active fractions were pooled and dialysed for 18 hours
20 against 20mM Tris-HCl, pH 7.6, to remove traces of ammonium
sulphate. The dialysed fractions were applied in 50 ml
aliquots to Q-Sepharose-High Performance in 20mM Tris-HCl, pH
7.6, at a flow rate of 4 ml per minute. Elution was by a 0-
0.2M gradient of KCl, the nitroreductase eluting at 0.1-0.12M
25 KCl. Active fractions were pooled and desalted into 20mM Bis
Tris propane, pH 7, using a column (32 x 6 cm) of Sephadex G25
medium. These fractions were applied to Q-Sepharose High
Performance (Hi-Load 26/10 column, Pharmacia) equilibrated in
20mM Bis Tris propane, pH7. Elution was by a 0-0.1M gradient
30 of KCl. Nitroreductase eluted as the first major peak at 0.07-
0.09M KCl.

Homogeneity of the final product was ascertained using precast
8-25% gradient gels for native polyacrylamide gel
electrophoresis (Pharmacia Phastsystem). Electrophoresis was
35 performed for 75vh.

The nitroreductase in crude and partially purified fractions was routinely assayed by its quinone reductase activity using menadione as substrate, NADH as co-factor and cytochrome C as terminal electron acceptor.

5 Determination of Isoelectric Point

The isoelectric point of nitroreductase was determined by isoelectric focusing (Pharmacia Phastsystem, focusing for 400 vh) and chromatofocusing using a Mono P column (Pharmacia Mono P HR5/20, 20mM Bis-Tris pH 6.3 and polybuffer 74, pH 4.0).

- 10 The E. coli nitroreductase was isolated as a pure protein with a molecular weight of 24kDa (as determined by both SDS-polyacrylamide gel electrophoresis and gel filtration chromatography). A second protein, which had quinone reductase activity but was inactive as a nitroreductase against
- 15 CB 1954, partially co-elutes from Phenyl Sepharose and can be fully separated from the active enzyme by the ion exchange chromatography step on Q-Sepharose high performance (see Table 1) at pH 7.6. The two enzymes differ in molecular weight (inactive 55KDa; active 24KDa) and isoelectric point (inactive
- 20 5.2; active 5.1). The active protein has a yellow coloration suggesting the presence of a flavin coenzyme. After heating at 70°C for 20 minutes this flavin could be separated from the apoenzyme by ultrafiltration and shown to be FMN, rather than FAD, using HPLC.

TABLE 1

The purification of a nitroreductase from *E. coli* B. The enzyme activity was assayed, at 37°C, by its quinone reductase activity using menadione (10 μ M) as substrate, NADH (500 μ M) as cofactor and cytochrome C (70 μ M) as terminal electron acceptor. A unit was defined as 1 μ mole of 5 cytochrome C reduced per minute.

FRACTION	TOTAL ACTIVITY (Units)	SPECIFIC ACTIVITY (Units/mg protein)	YIELD (%)
Crude	3784*	0.34	100
Phenyl Sepharose	2371*	1.6	63
10			
CB 1954	CB1954	CB 1954	CB 1954
ACTIVE	INACTIVE	ACTIVE	INACTIVE
1109	1262	30	33
Q-Sepharose			
(Tris, pH7.6)	-	79	18
15 Q-Sepharose			
(Bis-Tris propane, PH7)	310	130	8

*This includes activity from enzymes not active against CB 1954

Fragments suitable for sequence analysis were produced by digestion of the enzyme with cyanogen bromide. The peptides which resulted from these digests were purified by reverse-phase HPLC, using a RP 300 column (25 x 4.6 mm) (Brownlee) and
5 a solvent gradient of 10-60% acetonitrile in water with 0.06% trifluoroacetic acid in each solvent. Sequence analysis was performed by automated Edman degradation using an Applied Biosystems 470A gas phase protein sequencer (Kelvin Close, Warrington, U.K.).

10 Amino acid sequence analysis of the nitroreductase

The E. coli nitroreductase as isolated above was subject to amino acid sequence analysis. In contrast to the enzyme isolated from the Walker tumour, EC.1.6.99.2, the nitroreductase of the present invention was not blocked at the
15 N-terminus and gave a clear N-terminal sequence of 31 amino acid residues and a peptide, generated by digestion with cyanogen bromide, of a further 41 residues. These partial sequences are given in Table 2.

TABLE 2

Amino acid sequences of the N-terminus of the *E. coli* B nitroreductase and of a peptide obtained after digestion of the nitroreductase with cyanogen bromide (bold type) and a comparison with the deduced protein sequence of the nitroreductase from *Salmonella typhimurium* (Watanabe et al, 1990).

Nucleotide sequence of the nitroreductase gene

The nitroreductase gene of *E. coli* has been cloned and its nucleotide sequence determined by dideoxy sequence analysis of both strands. In Table 3 is shown the nucleotide sequence of 1167 base NruI/Pst fragment which contains an open reading frame of 651 nucleotides encoding the nitroreductase. Putative sequence of Shine-Delgarno and transcriptional termination signal are indicated.

EXAMPLE 2

Enzymatic reduction of CB 1954. CB 1954 (100 μ M and also containing [U-³H] CB 1954 at 1.6×10^5 dpm per nmole), NADH or NAD(P)H (500 μ M) were incubated with the active enzyme obtained
5 as described in Example 1, (generally 2 μ g/ml E. coli nitroreductase or 35 μ g/ml Walker NAD(P)H dehydrogenase (quinone) EC 1.6.99.2) in 10 mM sodium phosphate buffer (pH 7) under either air or helium. At various times aliquots (10 μ l) were injected onto a Partisphere SCX (110 x 4.7 mm) HPLC
10 column and eluted isocratically (2 ml/min) with 100mM NaH₂PO₄.

The eluate was continuously monitored for adsorption at 310, 260 and 360 nm and the spectra of eluting components recorded using a diode-array detector. Samples (0.5 ml) were collected and the tritium activity of each determined by liquid
15 scintillation counting. This separation system could resolve all the expected reduction products.

To confirm further the identity of any reduction products, the above reduction mixture was also injected onto an ODS-5 reverse phase HPLC column and eluted (1 ml/min) with a methanol
20 gradient (0-30% linear over 30 min, 30-100% linear over 10 min.) in 0.1 M sodium phosphate buffer (pH 7).

Reduction of CB 1954 by the E. coli nitroreductase resulted in the formation of two products, shown to be, by comparison of retention times and spectral characteristics with known
25 standards, 5-(aziridin-1-yl)-4-hydroxylamino-2-nitrobenzamide and 5-(aziridin-1-yl)-2-hydroxylamino-4-nitrobenzamide. No other CB 1954 metabolites were found. In further confirmation of the formation of both the 2 and the 4-hydroxylamines by the nitroreductase of the invention, 33 μ M of 4-hydroxylamine was
30 formed when 67 μ M of CB 1954 was reduced by the nitroreductase. In contrast 50 μ M of 4-hydroxylamine was formed by the reduction of 50 μ M of CB 1954 by the Walker NAD(P)H dehydrogenase (quinone). Based on initial rates of 4-hydroxylamine formation nitroreductase is 31.2 fold more active per mg protein than
35 NAD(P)H dehydrogenase (quinone) (or 62 fold more active by CB 1954 reduction) under the standard conditions used.

The rate of reduction of CB 1954 or product formation was the same when the co-factor was either NAD(P)H or NADH and when the reduction was performed under helium.

To show that the nitroreductase was producing a cytotoxic
5 species, the reduction of CB 1954 was carried out in the presence of V79 cells, which are insensitive to CB 1954. As shown in Table 4, a dramatic cytotoxic effect was observed in Hamster V79 cells - but only under those conditions in which the nitroreductase reduced CB 1954.

TABLE 4

The effect of CB 1954 on the survival of V79 cells in the presence of the E. coli B nitroreductase. All treatments were for 2 hours at 37°C and the cells were then plated out for their resulting colony-forming ability. The nitroreductase concentration was 2 µg/ml and NADH was used as a cofactor.

<u>TREATMENT</u>	<u>% SURVIVAL</u>	<u>% DRUG REDUCTION</u>

+ NR + CB 1954 + 500 µM NADH	0.024	72

EXAMPLE 3Substrate specificity of the E. coli nitroreductase enzyme

The ability of the E. coli nitroreductase of the invention to reduce nitro-compounds other than CB 1954 was determined by HPLC by following the decrease in the peak area of NADH resulting from its oxidation. The experiments were carried out as above but the aliquots were injected onto a Partisphere SAX (110 x 4.7 mm) HPLC column and eluted isocratically (1 ml/min) with 75mM NaH₂PO₄. The results are shown in Table 5.

10 TABLE 5

The relative rates of reduction of various nitrobenzamides and nitrobenzenes with E. coli nitroreductase enzyme. Reduction rates were determined by the resulting oxidation of NADH. All reactions were carried out at 37°C in air, with NADH (500µM) as electron donor, at an initial substrate concentration of 100µM.

<u>SUBSTRATE</u>		<u>RELATIVE RATE OF NADH OXIDATION</u>
		<u>NR</u>
	CB 1954	1.0
	2,4-dinitro-5-(2-hydroxy-ethylamino)benzamide	0.04

EXAMPLE 4Enzyme Kinetic and Inhibition Studies

Quinone reductase activities were assayed by a spectrophotometric method using menadione as a substrate and cytochrome c as a terminal electron acceptor as described in Knox et al, Biochem. Pharmacol., 37, 4671-4677, 1988. Initial rates of reaction were determined by linear regression analysis ($r > 0.995$) and kinetic parameters determined from the resulting plots as described by Roberts et al, Biochem. Pharmacol. 38, 4137-4143, 1989. Protein concentration was determined using the a conventional protein assay (Bio-Rad) calibrated against bovine serum albumin.

Kinetic parameters for the E. coli nitroreductase and Walker NAD(P)H, dehydrogenase (quinone) EC. 1.6.99.2, are given in Table 6. Although both enzymes have comparable K_m 's for CB 1954, the K_m of the nitroreductase for NADH is about 10 fold less than the Walker enzyme. The absolute rates of reduction of CB 1954 (i.e. under saturating conditions) by the two enzymes is their k_{cat} values and this is 90 fold higher for the E. coli nitroreductase. Menadione was also a substrate for both enzymes with little difference in their respective k_{cat} 's although the K_m of nitroreductase for this substrate was 60 fold higher.

Dicoumarol was an inhibitor of the nitroreductase. No kinetic parameters could be measured with respect to NADH. With respect to menadione, dicoumarol was an uncompetitive inhibitor with a K_i' of $1.90 \pm 0.38 \mu M$.

TABLE 6

Kinetic parameters for the E. coli B nitroreductase and Walker NAD(P)H dehydrogenase (quinone).

EXAMPLE 5

The ability of the E. coli B nitroreductase to activate compounds other than CB 1954 to a cytotoxic species.

As shown in Table 7, a large cytotoxic effect was observed in
15 human MAWI cells by the prodrugs CB 1837 and CB 10-107 but only under those conditions when the prodrug was reduced by the nitroreductase enzyme.

TABLE 7

The effect of enzyme-activated prodrugs on the survival of MAWI cells. 1 ml volumes of MAWI cells (2×10^5 /ml) were incubated with 50 μ M prodrug, 500 μ M NADH, and 10 μ g/ml the enzyme of Example 1. After a 2 hour incubation at 37°C, the cells were harvested and assayed for their colony forming ability, and the supernatant assayed for the concentration of remaining prodrug by HPLC.

20 EXAMPLE 6

PREPARATION OF 1,4-DIHYDRO-NICOTINIC ACID RIBOSIDE FROM EITHER NICOTINIC ACID RIBOSIDE OR NICOTINIC ACID RIBOTIDE

(i) Preparation of nicotinic acid riboside from nicotinic acid ribotide.

25 A solution of nicotinic acid ribotide (nicotinic acid mononucleotide) (Sigma, Poole, U.K.) (25 mg) in aqueous buffer (tris 100 mM; pH 8.5; MgCl₂; 2.5 ml), was treated with 2000 units of alkaline phosphatase, type VII-S (100 μ l; 20,000 units/ml) (Sigma) at 37°C for 1 hour. The alkaline phosphatase
 30 was separated from the digest by centrifugal molecular filtration (10,000 molecular weight limit; "Centricon 10"; Amicon, High Wycombe, U.K.). Dilutions (1:100) of the solution were analysed both before and after digestion with alkaline phosphatase by anion exchange high performance liquid
 35 chromatography (Partisphere 5-SAX column, eluted isocratically

with 0.1M NaH_2PO_4 , pH5, 1.5 ml/min, 10 μ l injection volume, monitored by UV absorbance at 260 nm). The parent compound eluted with a retention time of 1.18 minutes. Post digestion examination indicated that a complete conversion had occurred to give the novel title compound eluting with a retention time of 0.63 minutes, taken to be indicative of dephosphorylation, yielding the riboside.

(ii) Reduction of nicotinic acid riboside to 1,4-dihydro-nicotinic acid riboside.

- 10 The method of Jarman and Searle (1972) was adopted. The method was applied both to nicotinic acid riboside as produced above, and also to chemically synthesised material (Jarman 1969). Identical results were obtained with starting compound from either source of origin.
- 15 To an aqueous solution of nicotinic acid riboside (5 ml; 4 mg/ml) was added 50 mg sodium carbonate, 50 mg sodium bicarbonate, and 50 mg sodium hydrosulphite. The stoppered solution was incubated at 37°C for 1 hour and the reduction product separated by preparative reverse phase HPLC. The 5 ml
- 20 was injected onto a microorb 5 μ m C18 (10 x 250 mm) reverse-phase column (Rainin) and eluted by a gradient of methanol in water (0-100% over 30 minutes) buffered at pH 5 by 10mM $\text{NH}_4\text{CH}_3\text{COO}$ at 4 ml/min. The eluate was continuously monitored both by UV absorbance and by fluorescence and the reduction
- 25 product, (chromatographing with baseline resolution at a retention time of 12-13 minutes), was characterised by both its absorbance maximum at 326 nm (at pH5; 340 nm at pH7) and by its fluorescence (Gilson 121 fluorometer with wide band glass filters; excitation centred at 350 nm; emission at 450 nm),
- 30 neither of which properties are displayed by the parent compound. Eluates of 4 ml. of a 2mM solution (assuming an ϵ_{340} of 6200 (i.e. the same as NADH) were typical, indicating a yield of 2.7 mg i.e. approximately 13%. Prior to experimental usage, the preparations were analysed by analytical HPLC and
- 35 confirmed to be essentially pure.

EXAMPLE 7

The ability of 1,4-dihydro-nicotinic acid riboside to act as a cofactor for the E. coli nitroreductase.

10 The ability of the nitroreductase enzyme to be able to use a synthetic cofactor in place of NADH or NADPH for the reduction of CB 1954 is shown in Figure 1. The nitroreductase enzyme can use both 1,4-dihydro-nicotinic acid riboside and NADH with equal efficiency as cofactors for the reduction of CB 1954. In contrast Walker DT diaphorase cannot utilise this synthetic
15 cofactor. Therefore 1,4-dihydro-nicotinic acid riboside is a selective cofactor for the E. coli nitroreductase enzyme and cannot be used by mammalian DT diaphorase.

In the following Examples 8-12, "Silica gel" refers to
20 Merck silica gel 60, 70-230 mesh and Proton NMR spectra were obtained at 300 MHz in CDCl₃. Temperatures are in °C.

EXAMPLE 8

4-[Bis(2-chloroethyl)amino]phenylcarbamic acid 4'-nitrobenzyl ester:

25 To a stirred solution of 4-nitrobenzyl chloroformate (295 mg) in dry CHCl₃ (5 ml), a solution of 4-[bis(2-chloroethyl)amino]aniline hydrochloride (367 mg and NEt₃ (377 µl) in dry CHCl₃ (5 ml) was added over 5 min. After 1 hr the solution was kept at 20° for 18 hr, then evaporated. The
30 residue was chromatographed on a column of silica gel with CHCl₃ to give the title product as a yellow solid which recrystallized from benzene/petroleum ether as prisms, m.p. 111-112°. Yield, 361 mg (64%). Chemical ionization mass

spectrum with CH_4^+ ion at m/z 412 ($M + 1$, relative intensity 1.00) indicates $M = 411$. $\text{C}_{18}\text{H}_{19}\text{N}_2\text{O}_4\text{Cl}_2$ requires $M = 411$ (for Cl^{35} isotope). NMR: δ 3.57 (m, 4H, CH_2Cl or CH_2N), 3.69 (m, 4H, CH_2Cl or CH_2N), 5.28 (s, 2H, ArCH_2), 6.65 (d, 4H, ArH), 7.51 (d, 2H, ArH) and 8.23 (d, 2H, ArH).

EXAMPLE 9

4-[Bis(2-chloroethyl)amino]phenyl 4'-nitrobenzyl carbonate

A solution of 4-nitrobenzyl chloroformate (58 mg) in dry CHCl_3 (1.5 ml) was added to a stirred, ice-cooled solution of 4-[bis(2-chloroethyl)amino]-phenol hydrochloride (72 mg) and NET_3 (74 μl) in dry CHCl_3 (2 ml). After 18 hr at 21° , the solution was evaporated and the residue chromatographed on a column of silica gel with CHCl_3 /petroleum ether (3:2) to give the title compound which crystallized from EtOAc /petroleum ether as pale yellow prisms, m.p. $77-79^\circ$ (yield, 102 mg). FAB MS: ion at m/z 413 indicates $M = 412$ ($\text{C}_{18}\text{H}_{19}\text{N}_2\text{O}_4\text{Cl}_2$ requires $M = 412$). NMR (CDCl_3): δ 3.62 (m, NCH_2 or ClCH_2), 3.69 (m, NCH_2 or ClCH_2), 5.33 (s, ArCH_2), 6.64 (d, ArH), 7.05 (d, ArH), 7.59 (d, ArH) and 8.25 (d, ArH).

20 EXAMPLE 10

N-4-Nitrobenzyloxycarbonyl-actinomycin D:

Actinomycin D (AMD, 41 mg) in MeOH (5 ml) was hydrogenated over 10% Pd/C for 2 hr, then evaporated in vacuo. The residue under N_2 was dissolved in a solution of 4-nitrobenzyl chloroformate (18 mg) in dry CHCl_3 (1.5 ml) and a solution of NET_3 (10 μl) in CHCl_3 (1.5 ml) was then added. After stirring under N_2 for 24 hr, the catalyst was filtered off and the solution, after dilution with MeOH (200 ml), was aerated for 3 days. The solution was evaporated and the product was purified to remove AMD by semi-preparative HPLC twice on a 1 cm diameter column of reversed-phased C_{18} -bonded silica with a 50-100% gradient of MeCN in H_2O . The title compound was crystallised from ethyl acetate/petroleum ether as red prisms. Yield, 31 mg (66%). Electrospray mass spectrum: ions at m/z 1434.5 ($M + \text{H}$) and 1456.4 ($M + \text{Na}$) indicates $M = 1433.5$. $\text{C}_{70}\text{H}_{91}\text{N}_{13}\text{O}_{20}$

(lowest mass isotope) requires $M = 1433.65$. NMR gave the same signals as AMD plus $\delta 6.71$ (d, 1H, ArCH_2), 7.09 (d, 1H, ArCH_2) and additional signals in the aromatic region.

EXAMPLE 11

5 N-4-nitrobenzyloxycarbonyl-doxorubicin VI

Doxorubicin hydrochloride (2.25 mg) was dissolved in dimethylformamide (DMF) (0.3 ml) containing triethylamine (NEt_3) (0.55 μl) and a solution of 4-nitrobenzyl-4'-nitrophenylcarbonate (1.4 ml) in DMF (0.1 ml) was added. After 10 stirring in the dark for 3 days, the mixture was separated by HPLC on a column (1 cm. diam.) of C_{18} reversed-phase silica with a gradient of 25 to 100% MeCN in 0.01M formate buffer (pH 4.0). The principal red fraction was concentrated and rechromatographed with H_2O in place of the formate buffer. 15 Evaporation in vacuo afforded the product (2.1 mg) as an amorphous red powder. Electrospray MS: ion at 723 ($M+H$) indicates $M = 722$. $\text{C}_{33}\text{H}_{34}\text{N}_2\text{O}_{15}$ requires $M = 722$.

EXAMPLE 12

N-4-Nitrobenzyloxycarbonyl-mitomycin C

20 A solution of mitomycin C (36 mg) in dimethyl formamide (DMF) (2 ml) containing NEt_3 (14 μl) was added to 4-nitrobenzyl chloroformate (30 mg) and the mixture was stirred at 21° for 4 hr. After evaporation in vacuo, the residue was chromatographed on a column of silica gel with EtOAc to give 25 the title compound as a dark red solid (49 mg). Electrospray MS: ion at 514 ($M+H$) indicates $M = 513$. $\text{C}_{23}\text{H}_{23}\text{N}_5\text{O}_8$ requires $M = 513$.

EXAMPLE 13

Formation of actinomycin D by the action of the nitroreductase
30 upon prodrug V:

V (100 μM) and cofactor (500 μM NADH) were incubated with enzyme (2 $\mu\text{g}/\text{ml}$ E. coli B nitroreductase of Example 1 in 10 mM sodium phosphate buffer (pH7) in air at 37°C . At various

times, aliquots (20 μ l) were injected onto a Microsorb C18 reverse-phase (240 x 4.7 mm) HPLC column and eluted isocratically (1 ml/min) with 80% acetonitrile in water. The eluate was continuously monitored for absorption at 280 nm and the concentration of drug calculated by integration of the peak corresponding to this compound on the HPLC trace. Only when the enzyme was present was actinomycin D released from the prodrug.

Disappearance of the prodrug N-4-nitro-benzyloxycarbonyl-actinomycin D (V) and formation of actinomycin D during incubation with the *E. coli* B nitroreductase of Example 1 is shown in Figure 2.

EXAMPLE 14

The formation of mitomycin C by the action of the nitroreductase enzyme upon prodrug VII

Prodrug VII (100 μ M) and cofactor (500 μ M NADH) were incubated with enzyme (5 μ g/ml *E. coli* B nitroreductase of Example 1) in 10mM sodium phosphate buffer (pH7) in air at 37°C. At various times aliquots (10 μ l) were injected onto a Partisphere C18 reverse-phase (150x4.7mm) HPLC column and eluted isocratically (2.0ml/min) with 50% methanol in water. The eluate was continuously monitored for absorption at 260 and 340 nm and the concentration of the drugs calculated by integration of the peak corresponding to the compound on the HPLC trace.

Disappearance of prodrug VII and the formation of mitomycin C during this incubation is shown in Figure 3. Only in the presence of the enzyme is mitomycin C released from the prodrug.

EXAMPLE 15

Activation of prodrug I where R¹NH₂ = III and prodrug V by the nitroreductase:

Generation of cytotoxicity by the action of the *E. coli* nitroreductase of Example 1 upon the prodrugs

4-[bis(2-chloroethyl)amino]phenylcarbamic acid
4'-nitrobenzyl ester (I where $R^1NH_2 = III$) and N-4-nitrobenzyloxy-carbonyl-actinomycin D (V) are shown in Table 8.

5 TABLE 8

The effect of enzyme-activated prodrugs on the survival of V79 cells. 1 ml volumes of V79 cells ($2 \times 10^5/ml$) were incubated with prodrug, 500 μM NADH, and 10 $\mu g/ml$ enzyme. After a 2 hour incubation at 37°C, the cells were harvested and assayed for their colony forming ability, and the supernatant assayed for the concentration of remaining prodrug by HPLC.

<u>TREATMENT</u>	<u>% SURVIVAL</u>	<u>% DRUG REDUCTION</u>

25 EXAMPLE 16

Preparation and binding of Antibody: Enzyme Conjugate

Antibody:enzyme conjugate of A5B7 F(ab)₂: nitroreductase was prepared using the heterobifunctional agents succinimidyl 4-(p-maleimidophenyl)butyrate (SMPB) to insert active maleimide groups into the immunoglobulin, and 2-mercapto-[S-acetyl]acetic acid N-hydroxysuccinimide (SATA) to thiolate the E. coli nitroreductase. On mixing the proteins the maleimide groups react with thiols to form a thioether bond. The molar ratio of SMPB:immunoglobulin used was 10:1 and the molar ratio of

SATA:nitroreductase was 4:1. Antibody:enzyme conjugate thus prepared was isolated from high molecular weight aggregates and uncoupled components by gel filtration chromatography using a calibrated column (16 x 700mm) of Superdex G200. The column
5 was equilibrated in phosphate buffered saline (PBS) and eluted with the same buffer at a flow rate of 1.0ml/min. Fractions containing material corresponding in molecular weight to 2:1 and 1:1 conjugate (316KDa and 233KDa respectively) were pooled and rechromatographed on the same column and samples from
10 pooled fractions were run on 4-15% SDS-PAGE gels (Pharmacia Phastgels, run for 60vh) under non-reducing conditions together with calibration proteins. The conjugate was present as material with Mr 125 KDa (corresponding to 1:1 F(ab')₂:nitroreductase and higher molecular weight conjugates
15 together with less amounts of free F(ab')₂ and nitroreductase.

The enzymic activity of the conjugate was established by the routine assay using CB1954 as substrate. The conjugate was shown to bind to plates coated with 1µg/ml CEA antigen and to contain binding sites for both rabbit anti-mouse immunoglobulin
20 and rabbit anti-nitroreductase secondary antibodies (Figure 4). Samples of uncoupled F(ab')₂ and nitroreductase were used to confirm the specificity of the secondary antibody binding.

The antibody binding was determined using a standard horse radish peroxidase (HRP) colorimetric ELISA assay, with the
25 results being read at 405nm. The inverted open triangles on Figure 4 show that bound A5B7 F(ab')₂-nitroreductase conjugate can be detected with a goat anti-mouse immunoglobulin antibody, and the closed inverted triangles show that the conjugate is also detected by a rabbit anti-NR antibody (the anti-NR
30 antibody being detected via the use of a goat anti-rabbit immunoglobulin antibody. The controls shown in Figure 4 are: closed circles = binding of unconjugated A5B7 F(ab')₂; open squares = A5B7 F(ab')₂-NR conjugate detected with goat anti-rabbit immunoglobulin; closed squares = NR only detected with
35 rabbit anti-NR; open triangles = NR only detected with goat anti-mouse immunoglobulin.

EXAMPLE 17In vivo toxicity of prodrug.

The actinomycin D prodrug (AMDPD) of formula V was tested for toxicity in mice. Groups of 3 mice were given 1, 10 or 100 mg/kg body weight i.p. of AMPD, and two further groups of 3 mice were given 1 and 10 mg/kg body weight i.p. of actinomycin D (AMD) dissolved in arachis oil. A further group of 3 mice were untreated, and a final group of 3 mice were given arachis oil i.p. only.

10 The body weight of the mice were monitored over 9 days. The results are shown on Table 9. All mice treated with 10mg/kg of AMD were dead by day 1. A similar result was obtained with a dose of 5mg/kg. These data indicate that AMPDP is at least 20 to 100 fold less toxic than AMD. In practice, the toxicity of
15 AMPDP is likely to be even lower, since the preparation of AMPDP used contains about 1% unconverted AMD.

TABLE 9Toxicity of AMD and AMPDP

CLAIMS

1. A nitroreductase, obtainable from a bacterium having the following characteristics:
 1. It is a flavoprotein having a molecular weight in the range 20-60 Kilodaltons;
 2. It requires either NADH or NAD(P)H or analogues thereof as a cofactor;
 3. It has a K_m for NADH or NAD(P)H in the range 1-100 μ M; and
 4. It is capable of reducing either or both nitro groups of CB 1954 and analogues thereof to a cytotoxic form e.g. the hydroxylamine.
 2. A nitroreductase according to claim 1 obtainable from the cells of E. coli B, E. coli C, Thermus aquaticus, Bacillus amyloliquifaciens or Bacillus caldotenax.
 3. A nitroreductase having the amino acid sequence of Seq. ID No. 2.
 4. A DNA encoding for the nitroreductase of claim 3.
 5. A DNA according to claim 4 which comprises the residues 176 to 829 of the DNA of Seq. ID No. 1.
 6. An antibody capable of binding a nitroreductase according to any one of claims 1 to 3.
 7. An antibody according to claim 6 which is a natural or recombinant monoclonal antibody or fragment thereof.
 8. A conjugate of (i) a targeting agent for a tumour and (ii) a nitroreductase according to any one of claims 1 to 3, optionally in association with a pharmaceutically acceptable carrier or diluent.
 9. A conjugate according to claim 8 wherein the targeting agent is a monoclonal antibody which will bind a tumour-
-

associated antigen.

10. A compound of the formula (I) or (II):

or:

where R^1 and R^2 are groups such that the compound R^1NH_2 and R^2OH are cytotoxic compounds.

11. A compound according to claim 10 wherein the compound R^1NH_2 is a nitrogen mustard compound.

12. A compound according to claim 11 of the formula (IV):

where R' and R'' are H, F or CH_3 .

13. A compound according to claim 12 where R' and R'' are both hydrogen.

14. A compound according to claim 10 which is a phenolic nitrogen mustard.

15. A compound according to claim 14 of the formula (VIII):

16. A compound of the formula (V), (VI), (VII):

- 43 -

V

VI

VII

SUBSTITUTE SHEET

17. A pharmaceutical composition comprising a compound according to any one of claims 9 to 16 in association with a pharmaceutically acceptable carrier or diluent.

18. A compound of the formula (IX):

wherein R^3 is H, an acyl group or a hydrocarbyl group containing up to 6 carbon atoms.

19. A compound of the formula (X):

wherein X^1 and X^2 , which may be the same or different, are each $NHOR^5$ or NO_2 with the proviso that X^1 and X^2 are not both NO_2 , where R^5 is H or a carboxylic acyl or hydrocarbyl group and Y is H or $CON(CH_3)_2$.

20. A pharmaceutical composition comprising a compound according to claim 18 or 19 in association with a pharmaceutically acceptable carrier or diluent.

21. A system comprising (i) a conjugate according to claim 8 or 9 and (ii) a prodrug according to any one of claims 10 to 16; or a composition according to claim 17; or a nitro-precursor of a compound according to claims 18 or 19 or a

pharmaceutical composition comprising such a compound in association with a pharmaceutically acceptable carrier or diluent.

22. A system according to claim 21 for use in a method of treatment of the human or animal body.
23. The riboside of 1,4-dihydro-nicotinic acid, optionally in association with a pharmaceutically acceptable carrier or diluent.
24. A system according to claim 21 which further comprises (iii) the riboside according to claim 23 .
25. A system according to claim 24 for use in a method of treatment of the human or animal body.
26. A process for the production of a nitroreductase, having the following characteristics:
 1. It is a flavoprotein having a molecular weight in the range 20-60 Kilodaltons;
 2. It requires either NADH or NAD(P)H or analogues thereof as a cofactor;
 3. It has a K_m for NADH or NAD(P)H in the range 1-100 μ M; and
 4. It is capable of reducing either or both nitro groups of CB 1954 and analogues thereof to a cytotoxic form e.g. the hydroxylamine, which comprises disrupting a bacterial cell containing the nitroreductase and subjecting the cell contents to chromatographic separation and isolating the nitroreductase.
27. A process according to claim 26 wherein the cells are E. coli B , E. coli C , Thermus aquaticus , Bacillus amyloliquifaciens or Bacillus caldotenax.
28. A process for the production of a nitroreductase having the amino acid sequence of Seq. ID No. 2 which comprises expressing DNA encoding the nitroreductase in an

expression vector contained in a host cell, and recovering the nitroreductase.

29. A process for the production of a prodrug of formula (I) or (II) as defined in claim 10 or a prodrug of formula (V), (VI) or (VII) as defined in claim 16 which comprises reacting the corresponding drug precursor with 4-nitrobenzyl chloroformate under anhydrous conditions.

30. A process for making a compound of the formula (IX) according to claim 18 or a compound of formula (X) according to claim 19 which comprises subjecting the corresponding dinitro compound to the action of a nitroreductase according to any one of claims 1 to 3.

31. A process for making the riboside of 1,4-dihydro-nicotinic acid which comprises reducing nicotinic acid riboside.

32. A process for making a conjugate of a targeting agent for a tumour and an enzyme as defined in any one of claims 1 to 3 which comprised covalently linking the agent to the enzyme using a covalent linker.

33. A process according to claim 33 wherein the targeting agent is a monoclonal antibody.

34. A method of treatment of neoplasia in a human or animal host requiring such treatment which comprises administering to the host an effective amount of (i) a nitroreductase according to claim 1 or 3 conjugated with a targeting agent for a tumour; and (ii) a p-nitrobenzyloxycarbonyl compound of Formula I or II as defined in claim 10 or a compound of formula V, VI or VII as defined in claim 16 which is a prodrug for an anti-tumour agent

35. A method according to claim 34 wherein components (i) and (ii) are administered sequentially.

36. A method according to claim 34 which further comprises the administration of (iii) a ribotide or riboside of nicotinic acid or nicotinamide as cofactor for the enzyme.

37. A method for the treatment of neoplasia in a human or animal host requiring such treatment which comprises administering to the host (i) a nitroreductase according to claim 1 or 3 conjugated with a targeting agent for a tumour and (ii) an effective amount of a nitro compound which is a prodrug for an anti-tumour agents of the formula IX or X as defined in claims 18 or 19.

38. A method according to claim 36 which further comprises the administration of (iii) a ribotide or riboside of nicotinic acid or nicotinamide as cofactor for the enzyme.

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 34-38 are directed to a method of treatment of the human/animal body the search has been carried out and based on the alleged effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

ANNEX TO THE INTERNATIONAL SEARCH REPORT
ON INTERNATIONAL PATENT APPLICATION NO.

GB 9201947
SA 65801

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report.
The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information. 14/01/93
